Office Action Summary	Application No.	Applicant(s)	
	10/666,730	NARUKI ET AL.	
	Examiner	Art Unit	
	Kenneth J. Malkowski	2613	

-- The MAILING DATE of this communication appears on the cover sheet with the correspondence address --

Period for Reply

A SHORTENED STATUTORY PERIOD FOR REPLY IS SET TO EXPIRE 3 MONTH(S) OR THIRTY (30) DAYS, WHICHEVER IS LONGER, FROM THE MAILING DATE OF THIS COMMUNICATION.

- Extensions of time may be available under the provisions of 37 CFR 1.136(a). In no event, however, may a reply be timely filed after SIX (6) MONTHS from the mailing date of this communication.
- If NO period for reply is specified above, the maximum statutory period will apply and will expire SIX (6) MONTHS from the mailing date of this communication.
- Failure to reply within the set or extended period for reply will, by statute, cause the application to become ABANDONED (35 U.S.C. § 133). Any reply received by the Office later than three months after the mailing date of this communication, even if timely filed, may reduce any earned patent term adjustment. See 37 CFR 1.704(b).

Status

- 1) ☒ Responsive to communication(s) filed on 11/29/06.
- 2a) ☒ This action is **FINAL**. 2b) ☐ This action is non-final.
- 3) ☐ Since this application is in condition for allowance except for formal matters, prosecution as to the merits is closed in accordance with the practice under *Ex parte Quayle*, 1935 C.D. 11, 453 O.G. 213.

Disposition of Claims

- 4) ☐ Claim(s) _____ is/are pending in the application.
- 4a) Of the above claim(s) _____ is/are withdrawn from consideration.
- 5) ☐ Claim(s) _____ is/are allowed.
- 6) ☒ Claim(s) 1-8 is/are rejected.
- 7) ☐ Claim(s) _____ is/are objected to.
- 8) ☐ Claim(s) _____ are subject to restriction and/or election requirement.

Application Papers

- 9) ☐ The specification is objected to by the Examiner.
- 10) ☐ The drawing(s) filed on _____ is/are: a) ☐ accepted or b) ☐ objected to by the Examiner.
 Applicant may not request that any objection to the drawing(s) be held in abeyance. See 37 CFR 1.85(a).
 Replacement drawing sheet(s) including the correction is required if the drawing(s) is objected to. See 37 CFR 1.121(d).
- 11) ☐ The oath or declaration is objected to by the Examiner. Note the attached Office Action or form PTO-152.

Priority under 35 U.S.C. § 119

- 12) ☐ Acknowledgment is made of a claim for foreign priority under 35 U.S.C. § 119(a)-(d) or (f).
- a) ☐ All b) ☐ Some * c) ☐ None of:
1. ☐ Certified copies of the priority documents have been received.
2. ☐ Certified copies of the priority documents have been received in Application No. _____.
3. ☐ Copies of the certified copies of the priority documents have been received in this National Stage application from the International Bureau (PCT Rule 17.2(a)).

* See the attached detailed Office action for a list of the certified copies not received.

DETAILED ACTION

Claim Rejections - 35 USC § 103

1. The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:

(a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negated by the manner in which the invention was made.

2. Claims 1-3 and 7-8 are rejected under 35 U.S.C. 103(a) as being unpatentable over U.S. Patent No. 6,504,634 to Chan et al. in view of U.S. Patent No. 6,690,888 to Keller et al.

With respect to claim 1, Chan discloses an optical wireless communication system (column 5 lines 55-64 (nodes are interconnected with one another by optical communication links, it is preferable that said links are wireless communication links)) comprising a transmitter (1004, Figure 18) and a receiver (1002, Figure 18), said transmitter comprising: a first optical transmitting means for transmitting a first optical signal having narrow directivity (column 21 lines 40-49 (narrow beam width signal narrow beam waist and a small divergence)), said receiver comprising: a first optical receiving unit for receiving said first optical signal (column 5 lines 57-58 (nodes include one or more optical transmitters and receivers)) and converting said first optical signal into an electric signal (column 6 lines 10-11 (receivers use photodetectors)), a light-receiving level detecting unit for detecting a light-receiving level of said first optical signal received by said first optical receiving unit (column 6 lines 10-11 (receivers use photodetectors)); a second optical transmitting means for transmitting a second optical

Art Unit: 2613

signal (1008, figure 18) which carries light-receiving level information of said first optical signal obtained by said light-receiving level detecting means (column 34 lines 44-48 (signal strength received by receiver can provide said signal strength information back to the transmitter)) and has directivity wider than that of said first optical signal (column 28 lines 14-16 (a second transmitter 1008 has a wider beam of divergence than the first transmitter)); and said transmitter further comprising: a second optical receiving means (1010, Figure 18)(column 27 lines 62-65 (a second optical transmitter and receiver pair are included at either end of the communication link to facilitate alignment of the optical components) including a plurality of light-receiving elements each having light-receiving capability for receiving said second optical signal at a level corresponding to a difference in direction between an optical axis of said receiver and an optical axis of said transmitter (Figure 19)(column 30 lines 28-31 (quadrant detector with four quadrants))(column 28 lines 24-26 (quadrant detector offers spatial information about the received signal)); a drive means (column 10 lines 5-6 driving mechanics))(column 10 lines 39-44 (motor or other drive mechanism can be used to drive the gimbals)) for positioning said first optical transmitting means and said second optical receiving means by integrally shifting said first optical transmitting means and said second optical receiving means toward the direction of said receiver (column 11 lines 20-28 (pointing offset error is corrected by using drive means to correct for pointing error))(column 2 lines 13-19 (transceivers are fixed to a movable mount to facilitate pointing of a transceiver to another node in the network))(column 3 lines 25-28 (pointing of the transmitter can be adjusted)); a rough optical axis adjusting (column 27 47-50 (link

Art Unit: 2613

acquisition)) unit which executes a rough optical axis adjustment by controlling said drive unit so as to substantially equalize the light-receiving levels by said plurality of light-receiving elements (columns 29-30 lines 57-67 and 1-5 (Chan explains that the received optical axis is moved until the optical axis is centered on the detector thereby equally distributing the optical beam on all four light-receiving elements))(column 37 lines 1-7 (the initial step of alignment is rough or course pointing)); and a fine optical axis adjusting means for executing a fine optical axis adjustment (column 27 lines 57-61 (higher degree of pointing precision))(column 37 lines 25-30 (transmitter begins scan which is at worst a 10 degree by 10 degree uncertainty field wherein transmit beam can be centered on detector)) by controlling said drive means based on the information of the light-receiving level contained in the second optical signal being received by said second optical receiving means, after the rough optical axis adjustment by said rough optical axis adjusting means is accomplished (column 37 lines 14-31 (coarse pointing may not be enough to adequately acquire the transmitted signal, in this case finer adjusting is used))(column 35 lines 36-40 (if the received signal passes a threshold the transmitter is slewing in the correct direction to provide more accurate centering))(Figure 26).

However, However, Chan fails to disclose said fine optical axis adjusting means searches a relatively wide region when said light-receiving level information is relatively small, and said fine optical axis adjusting means searches a relatively narrow region when said light-receiving level information is relatively large. However, Keller, from the same field of endeavor discloses a method for establishing and maintaining optical

Art Unit: 2613

open-air communications links (title) wherein when transmitted light crosses a receiver area such that the detected light experiences an increasing intensity, the search scanning area is decreased (columns 10-11 lines 56-67 and 1-23 (if the intensity of the light in the new detected light event is greater than the prior intensity during the last event, the search area is narrowed." Because Keller clearly teaches searching a relatively narrower region for a relatively higher optical level the claimed condition is met)). Therefore, it would have been obvious to one of ordinary skill in the art to implement the optical signal scanning method as taught by Keller in the optical scanning method as disclosed by Chan. The motivation for doing so would have been to decrease the amount of overall scanning time while also verifying that optical intensity is high enough for accurate data transmission (Keller: column 11 lines 1-6).

With respect to claim 2, Chan in view of Keller discloses the optical wireless communication system in accordance with claim 1, wherein said plurality of light-receiving elements of said second optical receiving means are four photoelectric conversion elements arranged in a matrix pattern consisting of two lines and two rows in horizontal and vertical directions (column 11 lines 14-27 (quadrant PIN detector))(Figure 19 (two rows and two columns shown))(Figure 21 (two rows and two columns shown)), and said rough optical axis adjusting means executes the rough positioning of the optical axis in a total of eight directions based on the difference in the light-receiving level of said four photoelectric conversion elements (column 11 lines 18-27 (quadrant detector generates an error signal which is used to drive azimuth and gimbal motors to correct for the error))(column 10 lines 30-45 (gimbal/azimuth motors allow for pointing

bearings in a wide range of bearings, each node head is capable of rotating 370 degrees, other ranges are also permissible)).

With respect to claim 3, Chan in view of Keller discloses the optical wireless communication system in accordance with claim 1 (column 5 lines 55-64 (nodes are interconnected with one another by optical communication links, it is preferable that said links are wireless communication links)), wherein said fine optical axis adjusting means searches a region (column 37 lines 25-30 (scanning area has at worst a 10 by 10 degree uncertainty field)) wherein said light-receiving level information exceeds a predetermined value and executes the fine optical axis adjustment for the region identified by the search (column 37 lines 33-37 (once the corner cube is acquired, the beam can be directed to the receiver and the fine tuning can take place (wherein predetermined value is the value which allows for corner cube acquisition))).

With respect to claims 7-8 Chan in view of the optical wireless communication system in accordance with claim 1, wherein the fine optical axis adjusting unit (column 3 line 21 (fine tuning)) is adapted to execute the fine optical axis adjustment such that the light-receiving level of the first optical signal is maximized (column 3 lines 21-27 and 48-57 (optical axis can be adjusted to maximized (wherein a maximized optical communication signal is inherently above a communicable level) at the center of the spatial detector or minimized away from the center of the spatial detector))).

3. Claim 5 is rejected under 35 U.S.C. 103(a) as being unpatentable over U.S. Patent No. 6,504,634 to Chan et al. in view of U.S. Patent No. 6,690,888 to Keller et al. and further in view of U.S. Patent No. 7,016,612 to Ikeda et al.

With respect to claim 5, Chan in view of Keller discloses the optical wireless communication system in accordance with claim 1 (column 5 lines 55-64 (nodes are interconnected with one another by optical communication links, it is preferable that said links are wireless communication links)). However, Chan in view of Keller fails to disclose said fine optical axis adjusting means estimates a distance to said receiver based on said light-receiving level information, and accomplishes said fine optical axis adjustment. Ikeda, from the same field of endeavor estimates a distance between counterpart assemblies based on light receiving level information (column 13 lines 17-41 (reception light intensity of the optical communication device is inversely proportional to the square of the distance))(Figures 11 and 12) to perform fine optical axis adjustment (column 13 lines 37-41 (reception light intensity level is judged and emission intensity is then adjusted according to the communication distance)). Therefore, it would have been obvious to one of ordinary skill in the art to implement the distance measurement as disclosed by Ikeda. The motivation for doing so would have been to create a more diverse optical axis alignment system that can compensate for a varying transmission distance.

4. Claim 6 is rejected under 35 U.S.C. 103(a) as being unpatentable over U.S. Patent No. 6,504,634 to Chan et al. in view of U.S. Patent No. 6,690,888 to Keller et al. and further in view of U.S. Patent Application Publication No. 2002/0196506 to Graves et al.

With respect to claim 6, Chan discloses the optical wireless communication system in accordance with claim 1, however Chan fails to disclose halting transmission

Art Unit: 2613

of an optical signal until a level of light is received at the receiver. Graves, from the same field of endeavor discloses an optical wireless communication system (atmospheric optical data transmission system (title)) a wherein transmitting said first optical signal by said first optical transmitting means is stopped until the light-receiving level of said plurality of light-receiving elements of said second optical receiving means exceeds a predetermined value (page 9 paragraph 57 (components intermittently transmit and receive the light waves. When one transceiver is transmitting the other transceiver is only receiving and vice versa)). Therefore it would have been obvious to implement the halting transmission as taught by Graves in the communication system as taught by Chan. The motivation for doing so would have been to allow for time to adjust said transmission for non-ideal pulses such as pulses blocked by adverse atmospheric conditions (Graves: page 1 paragraph 2 (dust, smoke, fog))(page 1 paragraph 4 (system is adaptive to atmospheric aberrations)) and to save on optical power usage.

Response to Arguments

5. Applicant's arguments with respect to claim 1-8 have been considered but are moot in view of the new ground(s) of rejection.

However, there are several points that would be beneficial to address that were brought up by applicant in the response dated 11/29/06. With respect to claim 1, applicant states that the Chan reference fails to disclose an optical axis adjustment wherein levels of an optical signal in several light-receiving elements are equalized with one another on page 11 of remarks. Chan does, however clearly disclose this. A

Art Unit: 2613

quadrant detector like the one pictured in Figures 19 and 21 consists of the "multitude of light-receiving elements" with light receiving elements A-D. On columns 29-30 lines 57-67 and 1-5, Chan explains that the received optical axis is moved until the optical axis is centered on the detector thereby equally distributing the optical beam on all four light-receiving elements.

With respect to material formerly in claim 4, applicant states that Keller fails to disclose "executing a fine optical axis adjustment by searching a relatively wide region for a relatively low optical level and searching a relatively narrow region when during a relatively high optical level." However, Keller clearly does teach this on columns 10-11 lines 56-67 and 1-23, "If the intensity of the light in the new detected light event is greater than the prior intensity during the last event, the search area is narrowed." Because Keller clearly teaches searching a relatively more narrow region for a relatively higher optical level the claimed condition is met.

6. Applicant's amendment necessitated the new ground(s) of rejection presented in this Office action. Accordingly, **THIS ACTION IS MADE FINAL**. See MPEP § 706.07(a). Applicant is reminded of the extension of time policy as set forth in 37 CFR 1.136(a).

A shortened statutory period for reply to this final action is set to expire THREE MONTHS from the mailing date of this action. In the event a first reply is filed within TWO MONTHS of the mailing date of this final action and the advisory action is not mailed until after the end of the THREE-MONTH shortened statutory period, then the shortened statutory period will expire on the date the advisory action is mailed, and any

Art Unit: 2613

extension fee pursuant to 37 CFR 1.136(a) will be calculated from the mailing date of the advisory action. In no event, however, will the statutory period for reply expire later than SIX MONTHS from the date of this final action.

7. Any inquiry concerning this communication or earlier communications from the examiner should be directed to Kenneth J. Malkowski whose telephone number is (571) 272-5505. The examiner can normally be reached on M-F 8:30-5:00.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Ken Vanderpuye can be reached on (571) 272-3078. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.

Information regarding the status of an application may be obtained from the Patent Application Information Retrieval (PAIR) system. Status information for published applications may be obtained from either Private PAIR or Public PAIR. Status information for unpublished applications is available through Private PAIR only. For more information about the PAIR system, see <http://pair-direct.uspto.gov>. Should you have questions on access to the Private PAIR system, contact the Electronic Business Center (EBC) at 866-217-9197 (toll-free). If you would like assistance from a USPTO Customer Service Representative or access to the automated information system, call 800-786-9199 (IN USA OR CANADA) or 571-272-1000.
